

**Electrical coupling bar and adapted connecting device**

The present invention relates to the technical field of electrical appliances, for example of the modular type or  
5 another type, and also to the field of electrical cabinets in which such electrical appliances are utilised.

More particularly, the present invention concerns electrical cabinets that are intended, for example, to  
10 contain racks or other electrical subassemblies which are utilised, for example, in telecommunications.

It is often essential to feed electrical subassemblies disposed in an electrical cabinet via a circuit-breaker, in  
15 order to protect said subassemblies. The addition of circuit-breakers to these cabinets is often problematic, due to the space requirement which is associated, in particular, with the power supply and the provision of electrical connecting wires.

20

The object of the present invention is to eliminate these drawbacks and to bring about the feeding of electrical appliances via protection systems of the circuit-breaker type by facilitating the installation of said systems and  
25 by not increasing the space requirement associated with the use of said systems.

The objects assigned to the present invention are achieved with the aid of an electrical coupling bar including:

- 30       - an electrically insulating support exhibiting two parallel grooves,  
         - a metallic strip engaged in each groove, the metallic strips projecting out of the grooves and exhibiting interior faces opposite one another,  
35       delimiting between them a free engagement space for a connecting device, said free engagement space

being devoid of any element or of any part or  
extremity of said support,

- and protecting means covering the other faces of  
the metallic strips.

5

Such a coupling bar has a reduced space requirement and can  
be easily fastened to a support of the type constituted by  
walls of an electrical cabinet.

- 10 The metallic strips are not directly accessible and so  
enable accidents to be avoided in the course of  
interventions in the vicinity of the coupling bar.

- In addition, the manufacture of such a coupling bar is easy  
15 to implement and inexpensive.

The length of such a coupling bar can be adapted to the  
requirement by cutting it to the lengths necessary in the  
given applications.

20

Such a coupling bar may, moreover, be used with alternating  
currents or direct currents.

- According to an exemplary embodiment, the protecting means  
25 and the support are produced from a single piece. The  
number of parts contained in such a coupling bar is  
therefore limited.

- According to an exemplary embodiment, the metallic strips  
30 are inserted into the support. Assembly is realised in  
this way with a limited number of operations.

- According to another exemplary embodiment, the support is  
obtained by moulding of the metallic strips from a casting.  
35 The positioning tolerances of the metallic strips can then  
be reduced.

According to an exemplary embodiment, the support is realised with a material having a shape and a rigidity enabling the metallic strips to be immobilised.

5

Therefore no additional fastening means is needed.

According to an exemplary embodiment, the support includes a fastening component. This latter facilitates the mounting and the fastening of the coupling bar, for example in an electrical cabinet.

The fastening component is, for example, a projecting part approximately perpendicular to the interior faces of the metallic strips. This facilitates fastening on a wall parallel to said projecting part.

The present invention also concerns an electrical cabinet equipped with at least one electrical coupling bar as described above.

The present invention also concerns a connecting device intended to be engaged in a coupling bar exhibiting two metallic strips mounted in a support and delimiting between them a free engagement space, said device including a casing realised with an electrically insulating material and forming a housing provided with two input terminals for the connection of an electrical appliance of the circuit-breaker type, two connecting lugs projecting out of the casing, ensuring mechanical maintenance and the electrical link with the metallic strips after their introduction into the free engagement space, the electrical link being realised with metallic parts which are joined respectively onto a face of one connecting lug and onto an opposite face of the other connecting lug, each connecting lug being capable of establishing an electrical link with a specific

metallic strip, the casing being also provided with two power-supply terminals incorporating the electrical appliance into the power-supply circuit when a load or another appliance is connected to the power-supply terminals.

In this way it is possible to branch existing modular electrical appliances to the coupling bar via this connecting device, and to do this without adaptation.

According to an exemplary embodiment, the connecting lugs extend in a median extension plane of the housing. Such a configuration enables the positioning of the housing - and consequently of the electrical appliance which comes to be engaged in it - to be optimised in relation to the coupling bar and/or in relation to the electrical subassemblies mounted in an electrical cabinet.

Other characteristics and advantages will also become apparent from the detailed description provided below with reference to the drawings which are given by way of illustrative examples and in which:

- Figure 1 is a view in transverse section of an exemplary embodiment of a coupling bar according to the invention,
- Figure 2 is an exemplary embodiment of a connecting device according to the invention,
- Figure 3 is an exemplary embodiment of an electrical appliance intended to be inserted into the connecting device of Figure 2,
- Figure 4 is another exemplary embodiment of the connecting device according to the invention,
- Figures 5 and 6 are complementary views of the connecting device of Figure 4,

- Figure 7 is an example of the mounting of the connecting device according to the invention on the coupling bar according to the invention,
- Figures 8 and 9 each represent a face of an  
5 exemplary embodiment of a power-supply device of the coupling bar according to the invention,
- Figure 10 is another exemplary embodiment of the power supply of the coupling bar according to the invention,
- 10 - Figure 11 is a complementary exemplary embodiment of the power-supply device of the coupling bar according to the invention.

The invention concerns an electrical coupling bar (1),  
15 represented for example in Figure 1, including an electrically insulating support (1a) and exhibiting two parallel grooves (2).

A metallic strip (3) is engaged in each groove (2). The  
20 metallic strips (3) serve to realise electrical links and are produced from copper, for example. The metallic strips (3) project out of the grooves (2) and exhibit interior faces (3a) opposite one another, delimiting between them a free engagement space (4).

25 The free engagement space (4) is devoid of any element or of any part or extremity of the support. The space that is delimited in part by the interior faces (3a) is therefore entirely free and accessible for electrical-connection  
30 means and/or maintenance means. It is advantageous that the means that are utilised in order to establish an electrical link with the strips (3) are also utilised for mechanical maintenance on the coupling bar (1).

35 Means for electrical connection may in this way be engaged in the free engagement space (4). The coupling bar (1)

likewise includes protecting means covering the other faces of the metallic strips (3). It is a question of the exterior faces (3b), the lower faces (3c) and the upper faces (3d). In this way, metallic strips (3) are obtained  
5 that are inaccessible outside the free engagement space (4).

The parallel grooves (2) are separated by a central rib (5), defining the spacing of the metallic strips (3) which  
10 are immobilised in the support (1a), more particularly in the parallel grooves (2).

According to an exemplary embodiment, the protecting means and the support (1a) are produced from a single piece. The  
15 support (1a) therefore exhibits rising faces (1b) terminated by upper edges (1c) covering the upper faces (3d) and the exterior faces (3b). Only the interior faces (3a) opposite one another and projecting out of the parallel grooves (2) remain accessible inside the  
20 engagement space (4). The metallic strips (3) are therefore not accessible in the coupling bar (1) in normal use.

In order not to hamper the engagement of a connecting  
25 terminal in the coupling bar, the upper edges (1c) cover the upper faces (3d) over an approximately equal width. In this way a good mechanical maintenance of the metallic strips (3) is obtained without creating an edge extending into the free engagement space (4). The risk of direct  
30 accidental access to the metallic strips (3) is also reduced for the user.

The metallic strips (3) are, for example, inserted into the support (1a). The insertion is, for example, a force fit,  
35 enabling the metallic strips (3) to be immobilised in the

support (1a). The latter is produced from, for example, thermosetting or thermoplastic plastic.

According to another exemplary embodiment, the support (1a)  
5 is obtained by moulding of the metallic strips (3) from a casting. The support (1a) is then realised with a material having a shape and rigidity enabling the metallic strips (3) to be immobilised.

10 The support (1a) also includes a fastening component (1d) which enables the coupling bar (1) to be fastened to a base of the electrical-cabinet type. The fastening component (1d) is, for example, a projecting part approximately perpendicular to the interior faces (3a) of the metallic  
15 strips (3). The coupling bar (1) is, for example, fastened within an electrical cabinet (6).

The present invention also concerns a connecting device (7), represented for example in Figures 2, 4, 5 and 6,  
20 which is intended to be engaged in the coupling bar (1) described above. Engagement is effected in the free engagement space (4) in a direction approximately orthogonal to the longitudinal direction of extension of the metallic strips (3). Maintenance of the connecting  
25 device (7) is obtained by virtue of the friction between the interior faces (3a) and the corresponding parts of the connecting device.

The connecting device (7) includes a casing (8) which is  
30 realised with an electrically insulating material and which forms a housing (9) for an electrical appliance (10) of the circuit-breaker type.

The connecting device (7) includes two connecting lugs (11)  
35 and (12) projecting out of the casing (8) and ensuring mechanical maintenance and the electrical link with the

metallic strips (3). The connecting lugs (11) and (12) are therefore intended to be engaged in the free engagement space (4) of the coupling bar (1). The electrical link is realised with metallic parts (13) which are joined  
5 respectively onto a face of one connecting lug (12) and onto an opposite face of the other connecting lug (11). The metallic parts (13) are therefore disposed on a single face of each connecting lug (11) or (12). In this way each connecting lug (11) or (12) is capable of establishing an  
10 electrical link with a corresponding metallic strip (3) from the time of its introduction into the free engagement space (4).

The casing (8) is also provided with two power-supply  
15 terminals (14) and (15) integrating the electrical appliance (10) into the power-supply circuit when a load or another appliance having to be protected is connected to said power-supply terminals (14, 15). Input terminals (16, 17) are provided at the bottom of the housing (9) for the  
20 connection of the electrical appliance (10) subsequent to its positioning in said housing. In this way the power-supply terminal (14) is directly linked to the metallic part (13) which is intended to come into contact with one of the metallic strips (3), whereas the power-supply  
25 terminal (15) is directly linked to the input connecting terminal (17). The input connecting terminal (16) is directly linked to the other metallic part (13) which is intended to come into contact with the other metallic strip (3). When the electrical appliance (10), in the given case  
30 a circuit-breaker, is inserted with plug-in terminals (18) and (19) into the corresponding input terminals (17) and (16), an electrical power supply is obtained at the power-supply terminals (14) and (15) integrating said electrical appliance (10) into the electrical power-supply circuit.  
35 In this way the branching at the power-supply terminals (14) and (15) is secured by the electrical appliance (10),

in the given case a circuit-breaker (10). This latter is advantageously provided with a resetting lever (20).

The connecting lugs (11) and (12) advantageously extend  
5 within an offset extension plane which is parallel to a median extension plane (P) of the housing (9). This enables the positioning of the electrical appliance (10) and of the connecting device (7) to be optimised, and at the same time enables the space requirement of said  
10 subassembly in an electrical cabinet (6) to be reduced. Accessibility to the power-supply terminals (14) and (15) is also facilitated. The power supply may also be positioned at any place whatsoever on the coupling bar (1).

15 The electrical coupling bar (1) is fed electrically via a power-supply device, represented for example in Figures 8, 9, 10 or 11. Figures 8 and 9 represent, respectively, a front view and a rear view of such a power-supply device. This latter comprises two power-supply wires (21, 22), each  
20 of which is linked to a power-supply lug (23, 24) which is created from an electrically insulating support. Each power-supply lug (23, 24) is provided on one of its faces with a joined-on metallic part (13), enabling the electrical link to be established. This metallic part (13)  
25 is advantageously provided with parallel lamellae (13a), the cambered shape of which enables a mechanically stable and intimate engagement to be ensured between the metallic strips (3). The thickness of the power-supply lugs (23, 24), including the metallic parts (13), is therefore  
30 perfectly adapted to the clearance of the metallic strips (3).

Another example of a power-supply device is represented in Figure 10. In this exemplary embodiment the power-supply  
35 lugs (23, 24) extend approximately orthogonally to the direction of introduction of the linking wires (21, 22)

into said device. The wires 21, 22 are linked to the metallic parts (13) via any known means.

The metallic parts (13) described below are also suitable  
5 for the connecting device (7) described previously,  
represented for example in Figure 4.

Figure 11 represents an embodiment variant of a power-  
supply device which exhibits an engagement fitting (25) in  
10 which two routing zones (26) of the cables (21, 22) enable  
the connection with corresponding metallic parts (13) to be  
realised.

The fitting (25) is provided with a blocking arm (27), the  
15 extremity of which, overhanging the power-supply lugs (23,  
24), is provided with a clip (28). This latter is intended  
to be engaged behind at least one projection (1e) provided  
on a rising face (1b) of the support (1a). According to  
the example represented in Figure 11, the power-supply lugs  
20 23 and 24 are produced in a single piece. Linking contacts  
(30) enable the blocking arm (27) to be linked to the  
fitting (25) and enable an elastic deformation to be  
ensured in order to enable the engagement of the clip (28)  
behind the projection (1e). A pressure zone (29), provided  
25 on the blocking arm (27) at the opposite end of the clip  
(28), enables the disengagement of the fitting (25) from  
the coupling bar (1) to be facilitated. By action on the  
pressure zone (29), the clip (28) is released from the  
projection (1e). This latter may also be replaced by a rib  
30 (1f). The blocking arm (27) therefore enables a stable  
fastening to the coupling bar (1) of the power-supply lugs  
(23) and (24) to be guaranteed and, if need be, enables a  
definite polarity to be identified for the power supply of  
the electrical metallic strips (3).

The connecting device according to the invention may also be provided with an indicator means enabling the energising of said connecting device to be identified. This indicator means may be constituted by light-emitting diodes.

5

In this way the connecting device (7) and the power-supply means may be mounted at any point on the coupling bar (1).

Great flexibility in the layout of electrical appliances  
10 (10) in an electrical cabinet (6) is obtained in this way.

According to the examples represented in Figures 4, 5, 6 and 7, the connecting device (7) is also provided with a blocking arm (27), the description of which given above for  
15 the power-supply device is transposable in all points. The mountings of the connecting device (7) and of the power-supply device on the coupling bar (1) are therefore identical. A pressure on the pressure zone (29) suffices in order to release the clip (28) (Figure 6) from the  
20 connecting projection (7) of the coupling bar (1).
